ABSTRACT

Commercial banks have a crucial role for the allocation of economic resource in countries. Their main contribution is in the economic growth of the country through making available the funds for investors to borrow as well as financial deepening in the country. Corporate performance has been one of the most important issues of managers, investors, and analysts. This concern is connected to the significant role of the profitability of corporate organizations in general, and the banks in particular, on the potential growth of the economy as a whole. A study of the determinants of corporate profitability, therefore, could assist management, investors, and government to forecast and deal with the rising uncertainty of the globalized environment. The issue of the determinants of bank profitability is studied by different authors and academic and the purpose of this paper is to investigate the profitability behavior of bank-specific, industry related and macroeconomic determinants. The primary objective is to investigate the determinants of the profitability and to present all the debates through the literature review on the profitability of these important financial institutions, the banks. An important element of the macro-prudential analysis is the evidence of the internal and external factors and their relationship to the profitability of the banking sector and how this relationship is affected by institutional and structural characteristics. On the other hand internal factors of the banks influencing in the profitability are analyzed.

Contribution/ Originality

This study contributes in the existing literature to provide additional evidence for the factors influencing the bank profitability. This study is one of very few studies which have investigated empirically and statistically the financial system for the emerging economy of Albania.
1. INTRODUCTION

Commercial banks play a vital role in the economic resource allocation of countries (Ongore, 2013). They contribute to economic growth of the country by making funds available for investors to borrow as well as financial deepening in the country (Otuori, 2013). The financial system of the South Eastern European (SEE) countries is characterized by the dominant role of the banking sector, with the capital market segment for long-term finance being illiquid and, in some cases, underdeveloped, while non-bank financial intermediaries, such as life insurance companies and private pension funds, are still at an embryonic stage of development (Athanasoglou et al., 2006).

The Net income provides information on how well the bank is doing but the constrain on using it is that it not adjusted for the size of the bank. This makes it difficult to compare how well a bank is doing compared to one other.

In this way a basic measure of bank profitability is the return on asset (ROA) which corrects for the size of the bank. It is true that ROA provides useful and necessary information on bank profitability but this is not on the major interest of the bank’s owners (equity holders). They are more concerned about how much the bank is earning on their equity investment, an amount that is measured by the return on equity (ROE), the net income per currency of equity capital (Mishkin Frederic et al., 2009).

This paper seeks to examine the effect of bank-specific, and macroeconomic variables on the profitability. It focuses on two main directions: Firstly, the literature review on the bank profitability explains why banking activities and performance have attracted the attention of practitioners, policy makers, and researchers alike, making the investigation of bank profitability relevant issue today than in earlier times, secondly an overview of the banking sector in Albania and statistically it proves if the factors taken in analysis are significant and their relation to profitability providing proofs on which of this factors are significant.

2. LITERATURE REVIEW

Determinants of bank profitability can be divided in internal and external factors. Internal factors of bank profitability can be defined as those factors that are influenced by the bank’s management policy objectives and decisions. Management effects are the results of differences in bank management policies, decisions, objectives, and actions reflected in differences in bank operating results, including profitability. Zimmerman (1996) has mentioned that management decisions, particularly regarding loan portfolio concentration, were an important factor contributing in bank performance.

Researchers frequently attribute good bank performance to quality management. Management quality is assessed in terms of senior officers’ awareness and control of the bank’s policies and performance.

The study of Haslem (1968; 1969) showed that most of the calculated balance sheet and income statement ratios were significantly related to profitability in particular capital ratios,
salaries, wages, interest paid and received. The data were for all the member banks of the US Federal Reserve System in a two year study. He also stated that a guide for improved management should first emphasize expense management, fund source management and lastly funds use management.

Wall (1985) concludes that a bank’s asset and liability management, its funding management and the non-interest cost controls all have a significant effect on the profitability record. There is an abundant number of studies concluding that one of the primary factors influencing the bank profitability is the control on the expenses. The profitability can be improved through the expense management making this an opportunity for the banks to control it.

The level of staff expenses appears to have a negative impact on banks ROA in the study of Bourke (1989) even though Molyneux (1993) found a positive relationship between total profits and staff expenses.

External determinants of bank profitability are concerned with those factors which are not influenced by specific bank’s decisions and policies, but by events outside the influence of the bank. Several external determinants are included separately in the performance examination to isolate their influence from that of bank structure so the impact of the former on profitability may be more clearly discerned.

The use of GDP growth as a variable does not feature extensively in the literature. However, Hoggarth et al. (1998) conclude that the behavior of real GDP fails to explain the greater variability of banking sector profits in the UK than in Germany. But they do not say that GDP variability did not affect profits, only that they could not use it to explain different UK/German banks performance.

If this variable is not statistically significant in explaining profitability, then the conclusions of the authors are reinforced. Otherwise, the expected sign should be positive since higher growth implies both lower probabilities of individual and corporate default and an easiest access to credit.

The effects of inflation can be substantial and undermines the stability of the financial system and the ability of the regulator to control the solvency of financial intermediaries. Revell (1979) noted that variations in bank profitability can be strongly explained by the level of inflation.

3. THE CURRENT ISSUES ON THE BANK PROFITABILITY IN THE BANKING SYSTEM

According to IMF Website –Global Financial Stability Report (2014), until now, banks have focused primarily on raising capital and de-risking their balance sheets to meet risk-based requirements. Their focus, however, has now broadened to include other elements of the Basel III regime, often ahead of the mandated schedule (Figure 1).

The new liquidity requirement as per Basel III (example the liquidity coverage ratio and the net stable funding ratio) will imply the banks to rely more on more on stable funding sources and to hold more liquid assets which has lower risk.
In this new environment with new regulatory requirements and lower profitability due to these requirements, banks need to find a way in order to ensure they can meet and maintain the capital buffers meeting the credit demand and without taking excessive risk.

During the past few years the measures that the banks have taken to face these challenges were: rising capital, cutting operating costs or selling noncore businesses. In this view more needs to be done because there may be limited space for other ways to face these challenges.

4. THE BANK PROFITABILITY IN ALBANIA

The profitability of the banking sector in Albania results to be high, compared with the Western Balkan countries. The values of the indicators of return on assets (ROA) and equity (ROE) remain significantly above the regional average, respectively 0.88% and 8.04%. The level of capitalization of our banking sector is satisfactory, and the capital adequacy indicator turns close to the regional average (17.5%), which is characterized by high values of this indicator. Meanwhile, asset quality remains a major problem as the banking sector and for a part of the Western Balkan countries. However, in our case, the index of non-performing loans resulting on average in the region of 16.2%. In the following part of the paper is presented the empirical result of the banking system indicators of performance and factors influencing in it. In the literature its quiet common to find as a result that the bank profitability is increased when the loan portfolio is increased related to other more secure assets. This greater relative proportion of loans in the portfolio of the bank is usually coupled with a greater liquidity risk arising from the inability of banks to accommodate decreases in liabilities or to fund increases on the assets side of the balance sheet. In Albania the level of total loans has increased during the years (graphic below). According to the literature that should be accompanied with an increase of performance or profitability because higher levels of
loans means higher incomes from the interest of the loan. In our country the result is negative. The figures shows that the increase of the loans’ level is not accompanied with the increase of profitability. This might be explained with the increase of the NPL ratio and provision expenses.

The level of non performing loans has increased dramatically over years. The increase of the NPL is accompanied with increase of provisions from the bank resulting in the decrease of profitability. Even if we take in consideration the literature on the issue on the relationship that exist asset quality and profitability there appears to be a consensus that bank profitability is directly related to the quality of the assets on its balance sheet; which means poor credit quality has a negative effect on bank profitability and vice versa. This relationship is explained with the fact that an increase in the assets classified as doubtful will bring an allocation of more provisions expenses to cover the credit losses which means lower bank profitability.
According to the literature a higher share of customer deposits in bank liabilities should increase a bank’s profitability, considering that deposits constitute a cheap and stable financial resource compared with other financing alternatives (Claeys and Vander Vennet, 2008; García-Herrero et al., 2009) Thus, we examine whether there is a direct relationship between the proportion of customer deposits in a bank's total liabilities and the bank’s profitability.

On the other hand, an aggressive competition policy could lead banks to pay higher rates to attract deposits from competitors (the so-called “deposit war”), thus squeezing bank margins. If we analyze the ratio of the deposit to total liabilities of the bank (graphic below) we see that this ratio has been volatile through the years. Both the theories apply in the Albanian banking sector. The “deposit war” has happened among the banks effecting the bank margin. On the other hand this deposit war has happened because as it is explained in the literature the deposits constitute a cheap and stable financial resource. Though we expect that this factor should not explain the change of profitability or said in other words in the future empirical and econometric analysis it is expected that the factor of deposit to total liabilities of the bank to be not significant.
According to the external factors that influence the banking sector we analyze the GPD and inflation rate.

During the years the GDP of the country has had an upward slope even though the increase has been in low levels. According to the literature it is expected that the relationship between GDP and profitability to be positive. When the economy conditions are poor this is associated with low quality of loan portfolio. This brings the increase of credit losses and provisions expenses translated in lower profitability. Whereas good economic conditions is associated with the increase of demand for loans, better solvency of the borrower influencing positively in the bank profitability.

According to the literature, Revell (1979), introduces the relationship between bank profitability and inflation, stating that the effect of inflation on bank profitability depends on how inflation affects both salaries and the other operating costs of the bank. The study of Perry (1992) suggests that inflation impacts bank profitability whether it is fully anticipated or not. If the inflation rate is fully anticipated by the bank’s management, the bank can adjust interest rates appropriately to increase revenues faster than costs, which should have a positive impact on profitability. Also Demirgüç-Kunt and Huizinga (1999) notice that banks in developing countries tend to be less profitable in inflationary environments, particularly when they have a high capital ratio. Their study related to these countries shows that the costs of the banks are increased faster compared to the revenues.

The bank of Albania has tried to maintain the level of inflation between some target points. As it is seen from the graphic through the period 2007-2014 the range level of inflation rate has been 1.63-3.6%.
5. REGRESSION ANALYSIS

Profitability (ROE) = β0 + β1LQR + β2 NPL + β3LN + β4GDP + β5INF + ε

In this study the Profitability is the dependent. In Table 1 we have explained the dependent and independent variables along with their proxies.

<table>

| Source: Authors calculations |

The results shows that almost all the factors were significant, whereas the sign of the relationship between the dependent and the independent variable is explained as below:

1. NPL ratio: The result of the multi linear regression model shows that this factor is not significant to explain the bank profitability. The banks in Albania have had a high level of NPL ratio in the recent years, meaning a bad quality of the loan portfolio.
This is associated with an increase of the expenses for provisioning and lower ROE. Statistically this factor is related negatively to the ROE which is relevant. As we explained before the literature shows that this factor is significant to explain the profitability of the banks but in the case of Albania it is not. This is because the loan portfolio quality has been deteriorated in the recent years and even though the increase rate of NPL was smaller compared to previous years, it was because the decrease of the credit in the economy. In the same time, banks to improve the liquidity has had in focus to increase the deposits which we see in the factor we had included in our study, the ratio deposit to loans.

2. Deposit/Loans ratio: the result of the regression analysis shows that this factor is significant and related positively. We included this ratio in order to see the impact of the liquidity of the banks in the profitability. The beta coefficient is relatively small but positive meaning that if the banks increase the financing of the loans with deposits it will impact positively the ROE.

3. GDP level: The GDP is a factor that is significant and related positively to the profitability. In our analysis, GDP is an external factor, and for its relevancy it is considered as important to be taken in consideration. The increase of the GDP of the country has positive impact in the profitability of the banking sector in Albania associated with the other internal factors that are analyzed.

4. Inflation rate: The inflation appears to be significant and related negatively to the profitability. We mentioned that the results of the other authors were mixed for the impact of the inflation to the profitability. In the Albanian financial sector it appears that with the inflation the operational costs are increased more than the effect of the interest rates resulting in lower profitability for the banks.

5. Loans: The total loan level appears to be a significant variable in determining the ROE with negative sign. This is because the impact of the bad quality of loans portfolio which we mentioned is a problematic issue in this market with high level of NPL and high level of provision expenses.

Summarizing we could say that expect the NPL ratio, all the factors taken in analysis were significant for the selected data. The estimated results suggests that the profitability of Albanian banks is influenced not only by factors related to their management decisions which are classified as internal factors, but also to changes in the external macroeconomic environment i.e GDP, inflation which resulted as significantly related to profitability of the banks.

7. CONCLUDING REMARKS

We believe that testing for the robustness of banks performance over time and space should shed light on policy debates, and on the assessment of banks performance. In addition, we believe that the work has some relevance and importance for the ongoing wave of consolidation banking
markets and for the well-functioning of it. A linear function of a multiple regression equation, on a pooled cross section time series sample, is utilized in the desperation of the thesis to test the effects of firm and market specific variables on bank profitability. There is a number of studies with the focus of determining the factors that influence the bank profitability. These factors are classified as internal and external factors. Internal factors like portfolio composition and the type of operations performed in a bank can affect the operational costs which have a direct impact on the bank profitability. We perform time series regressions and year-by-year cross sectional regressions. The estimated results suggests that the profitability of Albanian banks is influenced not only by factors related to their management decisions, internal factors, but also to changes in the external macroeconomic environment. The type of explanation for the level of profitability would determine possible policy implications and ought to be taken seriously. Since very little empirical work has been undertaken investigating the competitive behavior of Albanian banking systems, an empirical investigation like the one conducted above may yield insights that could be of interest to academics, bankers, and policy makers.
